a priority for the city since the early 1950s. The FMC decided in early 1953 that radioactive waste from some city operations would be contained and segregated from solid wastes, but the BOC and the city of Philadelphia soon recognized that such a program would require a major overhaul of the city's waste management system. With the assistance of the South Philadelphia-based radiological waste operator, the city followed a three-pronged approach in response to the threat of the dangers of nuclear power. First, the city and the BOC established a state-of-the-art research center to develop material handling and treatment procedures for radioactive waste. Second, the operation and maintenance of the 13-story kraft paper production facility moved to the city, allowing the material to be safely segregated from the rest of the city's solid wastes. Finally, the establishment of the Emergency Operations Center during the mid-1950s, the development of special training programs for city employees, and the development of organizational and communication structures during the first several years following the accident served to equip City officials with the requisite skills to deal with a radiological emergency. Any disaster, whether local or global, has consequences that are varied and far-reaching. In response to a terrorist nuclear attack, an urban area would undoubtedly experience casualties, property damage, and other "real" consequences. Under these circumstances, however, the fallout would be vast and widespread and could have significant potential for large-scale public health and environmental problems. Fallout is the result of the release of radioactive particles into the air from a nuclear event. Its effects are not instantaneous, since the material does not instantly and completely disintegrate. Rather, the radiation will disperse over time, depending on the manner in which the radioactive particles are released. After the radiation particles fall to the ground, they gradually decay into ordinary materials. This decay process produces particles of a new chemical element, element I\ for example, where the nucleus of an atom has lost a neutron and a proton, leaving a nucleus with an odd number of protons and neutrons. The positive charge on the nucleus is balanced by the negative charges on the electrons; therefore, element I\ is electrically neutral. Just as radioactive particles degrade, radioactive particles are themselves decaying. Thus, they are
