The effects of maternal diabetes on fetal and neonatal kidney structure and function are reviewed. The mechanisms of increased susceptibility of the offspring of diabetic mothers for renal diseases in later life are considered. Major differences in fetal and neonatal kidney structure and function can be observed between normal and diabetic pregnancies. Growth of fetuses from normal diabetic mothers is retarded at birth. Changes in the hormonal status of diabetic mothers influence fetal kidney development. Insulin treatment ameliorates these structural changes. Similarly, hyperglycemia causes fetal and neonatal kidney structural changes which are also ameliorated by insulin. In the neonate, functional alterations of neonatal renal system such as gluconeogenesis, sodium reabsorption, and water excretion are accelerated. The kidney is a sensitive target organ for the detrimental effects of hyperglycemia. It is suggested that fetal and neonatal changes in kidney structure and function may predispose offspring of diabetic mothers to renal diseases in later life.[Elongation of the phylloquinone-vitamin K1-K2 chain in the prevention of phylloquinone deficiency in obese children treated with vitamin K1]. The effect of
